## Inspections and Inspection Systems

Inspection: "A formal or official examination"

Goal of individual inspection:

**Detect non-compliance**

Goal of inspection system:

**Deter/dissuade non-compliance as a strategy**

## Inspection System Elements

### Policies (what to inspect)

- Targeting (**red lane** / **green lane**)
- Random inspection (percentage of objects)

### Procedures (how to inspect)

- Layered inspections
- Onsite/offsite inspections

The right **mix** of targeted and random inspections can balance sunk cost against risk.

## Inspection as a Game

The inspector and the owner of the inspected object act **intelligently** and **interdependently**.

### Non-compliance motives

- Cost savings (safety/security violations)
- Economic payoff (smuggling)
- Political advantage (terrorism)

Inspection policy balances sunk cost vs expected loss.

Both parties choose strategy to **maximize payoff / minimize loss**.

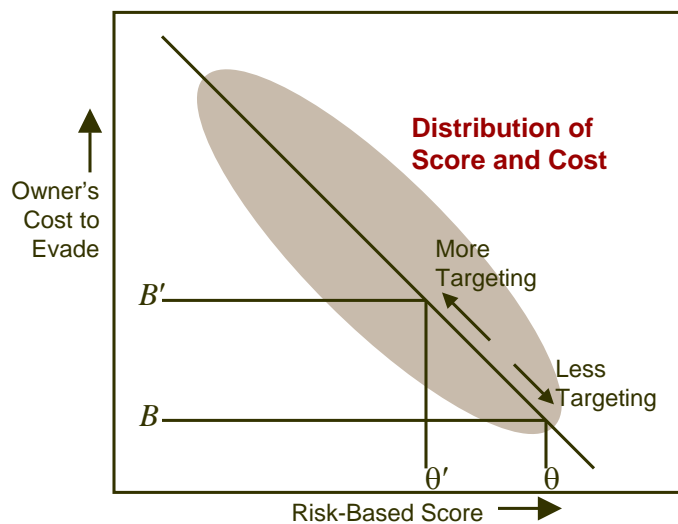

## Impact of Targeting and Random Inspection

How do **targeted** and **random** inspection impact effectiveness?

Ground rules:

- Available budget for inspection is **fixed**
- Targeting designed to identify objects associated with **greater risk**
- Owner **exploits** any known targeting rules
- Owner's strategies:  
**Comply, confront** targeting, or **evade** targeting
- Inspector enforces **penalties** for non-compliance

## Impact of Targeting

## Impact of Random Inspection

### Impact

- Budget drawn away from targeted inspections
- Owner's cost to evade targeting **decreases**
- Advantage owner gains by evading **decreases**

Uncertain: Does random inspection lower risk?

**Risk assessment requires a sophisticated approach.**

## Container Inspection: Process Model

- (1) Document Inspection
- (2) Non-Invasive Inspection (5-10 min)
- (3) Physical Inspection (~3 hr)
- (S) Random Selection

- $P(W)$  = Pr(weapon)
- $P_s$  = Pr(random selection)
- $\alpha_1$  = Pr(false alarm given (1))
- $\alpha_2$  = Pr(false alarm given (2))
- $\beta_1$  = Pr(miss given (1))
- $\beta_2$  = Pr(miss given (2))

## Container Inspection: Payoff

Challenge: Determine the most effective mix of targeted and random inspection rates, given fixed total inspection rate,  $\alpha$ .

		Red							
		Comply	Threaten						
Blue	Target	0	<table border="1"> <thead> <tr> <th>Confront</th> <th>Evade</th> </tr> </thead> <tbody> <tr> <td><math>A_T</math></td> <td><math>A - B_\alpha</math></td> </tr> <tr> <td><math>-D_T</math></td> <td><math>-D</math></td> </tr> </tbody> </table>	Confront	Evade	$A_T$	$A - B_\alpha$	$-D_T$	$-D$
	Confront	Evade							
$A_T$	$A - B_\alpha$								
$-D_T$	$-D$								
Randomize	0	$-D_\alpha$	$A_\alpha$						

Red Payoffs:  $A - B_\alpha$   
Blue Payoffs:  $-D$

•Factors taken into account:

$A$  = Assured attack payoff (political)

$A_T$  = Expected attempt payoff if targeted

$A_\alpha$  = Expected payoff w/random inspection ( $A_T < A_\alpha < A$ )

$B_\alpha$  = Additional cost to evade targeting

$D$  = Damage loss from attack

$D_T$  = Expected loss from attempt if targeted

$D_\alpha$  = Expected loss w/random inspection ( $D_T < D_\alpha < D$ )

MORS HLD-HCS Decision Support Workshop

## Container Inspection Pure Strategy Solutions

		Red							
		Comply	Threaten						
Blue	Target	0	<table border="1"> <thead> <tr> <th>Confront</th> <th>Evade</th> </tr> </thead> <tbody> <tr> <td><math>A_T</math></td> <td><math>A - B_\alpha</math></td> </tr> <tr> <td><math>-D_T</math></td> <td><math>-D</math></td> </tr> </tbody> </table>	Confront	Evade	$A_T$	$A - B_\alpha$	$-D_T$	$-D$
	Confront	Evade							
$A_T$	$A - B_\alpha$								
$-D_T$	$-D$								
Randomize	0	$-D_\alpha$	$A_\alpha$						

Under restricted conditions, pure strategy solutions are possible:

$(A_\alpha < 0, B_\alpha > A)$ or $(A_T < 0 < A_\alpha, B_\alpha > A - A_T)$ – “Deterred adversary” Red’s losses outweigh any expected gains. Blue must inspect enough to ensure threatening strategies do not pay off.
$(A_T > 0, B_\alpha > A - A_T)$ – “Confronting adversary” Red’s gain vs targeting outweighs cost, but evasion is not worth added cost. Blue must inspect enough to ensure evasion is not worth added cost.
$(A_\alpha > 0, A - B_\alpha > 0)$ – “Randomizing inspector” Red gains against random inspection by threatening. Red also gains by evading, so Blue does not target in order to limit damage.

MORS HLD-HLS Decision Support Workshop

## Container Inspection Mixed Strategy Solutions

Blue	Red							
	Comply	Threaten						
Target	0	<table border="1"> <thead> <tr> <th>Confront</th> <th>Evade</th> </tr> </thead> <tbody> <tr> <td><math>A_T</math></td> <td><math>A - B_\alpha</math></td> </tr> <tr> <td><math>-D_T</math></td> <td><math>-D</math></td> </tr> </tbody> </table>	Confront	Evade	$A_T$	$A - B_\alpha$	$-D_T$	$-D$
	Confront	Evade						
$A_T$	$A - B_\alpha$							
$-D_T$	$-D$							
Randomize	0	$A_\alpha$						

Otherwise, mixed-strategy solutions are recommended:

$(A_\alpha < 0 < A - B_\alpha)$  or  $(A_T < A - B_\alpha < 0 < A_\alpha)$  – “Dissuaded adversary”

Each chooses to make opponent indifferent to alternatives.

Blue mixes strategy to make Red indifferent to comply or evade.

Red mixes strategy to make Blue indifferent to target or randomize.

## What We Can/Should Do

- Traditional risk analysis is not enough.
- Game theory, with risk analysis, can help quantify cost, risk, and tradeoffs.
- Game theory can also identify policy decisions that drive an opponent's strategy in a desired way.
- What's Next:
  - Incorporate data into a game-theoretic model
  - Incorporate uncertainty in payoffs
  - Expand range of inspection strategies
